

24th STREET REALTY - MARKETING ANALYTICS

FIRM DESCRIPTION AND BACKGROUND

We began our search for data sets by reaching out to several local businesses—including Tiff's Treats, Verts, and 24th Street Realty—and gauging their interest in turning their raw data into valuable insights. We were pleased to find that 24th Street Realty, which had been collecting data for the past three years with the hopes of one day analyzing it, was both willing and eager to share its sales and marketing data with us.

As a real estate brokerage firm, 24th Street Realty offers a 100% free service to students, professors, and others looking to buy, sell, or lease in the Campus and Central Austin area. Its income comes primarily from referral fees, which are allocated according to property management companies' marketing budgets. As a free service, its success is heavily dependent on the quality of its agents and the connections they make. While 24th Street Realty's agents have been rated #1 by UT students since its founding in 2013, competition among both agents and brokerage firms remains high. Within the firm, "leads" are either generated personally by the agents or through the office. The firm defines a lead as anyone expressing interest in their services, whether that be a walk-in appointment, a client referral, or a completed interest form online. Personal leads belong to whoever generates them and office leads are distributed evenly among each agent through an automated, third-party system. On a larger scale, 24th Street Realty's competition includes West Campus Living, Property Management of Texas, Uptown Realty, 512 Realty, and individual leasing offices at various properties in the area. The firm's prime location in the offices above Starbucks, on the corner of 24th Street and San Antonio Street, gives it a competitive edge and has contributed to its success in garnering the highest number of walk-in clients in the campus area.

In addition to visibility, 24th Street Realty relies on several web-based promotions to generate leads including Twitter and Facebook accounts, a website, and a blog. Lori, the Marketing and Business Development Manager, posts leasing information as well as content relevant to college students--their largest demographic--on these platforms. While these accounts illicit a fair amount of engagement and reach to the firm's followers, its most popular form of promotion is word of mouth. Leasing agents still rely heavily on repeat clients and existing client referrals to generate new leads despite the firm's active presence on multiple social platforms.

DATA

Our data was given to us by Chris Zaiontz and Lori Kendall, the Leasing Manager and the Marketing and Business Development Manager at 24th Street Realty. They had been collecting data over the past three years, but were unsure how to analyze and learn from it. They shared two Dropbox folders with us containing "Leasing and Sales Numbers from 2013-2016" by month

and a “Social Media Analytics” folder that contained reports generated by Sprout Social, a social media management tool, pulled monthly from Twitter and Facebook for 2016.

The social media analytics folder contained data counts such as: incoming messages, sent messages, new Twitter followers, new Facebook fans, post engagement, link clicks, and impressions. The average number of Twitter engagements per month is 282.6, while the average number of Facebook engagements per month is 162.4. Thus far in 2016, 24th Street Realty has tweeted an average of 46 tweets per month and posted an average of 21.9 Facebook posts per month. The average number of impressions per month for Facebook and Twitter had the highest counts, with 5,267.7 and 29,454.1 respectively. After removing outliers from the data though, the average number of impressions per month for Twitter lowered to 8,637.33.

The leasing and sales numbers contained data counts and percentages such as: number of leads, number of appointments, lead-to-appointment ratio, number of deals, close rate, and amount (\$) invoiced. The average number of office leads per month is 269, while the average number of agent leads per month is 65. The average number of appointments made per month is 153, while the average number of deals made per month is 82. In relation to these numbers, the company was able to calculate lead-to-appointment ratios and close rate ratios, with their averages per month being 47.87% and 55.94% respectively. Lastly, the average invoice per month for 24th Street Realty is \$53,314.

The data from the social media analytics folder was formatted as PDF reports with multiple graphics explaining the data. The leasing and sales numbers were formatted as CSV files organized by year, month, and agent. We combined all of this raw data manually in excel in multiple formats for ease of analysis when using Solver and the Data Analysis Toolpak.

MARKETING ANALYTICS QUESTIONS

Our goal in this project was to determine if 24th Street Realty’s current marketing methods and lead allocation system contributed to the amount invoiced each month. We also wanted to create a model that would allow the firm to measure seasonality, predict future monthly invoices, and hire agents accordingly. By achieving these goals, we hoped to provide actionable recommendations supported by the firm’s own data. These are the specific questions that we sought to answer in our analysis:

1. What is the seasonality of sales?
2. What is the sales trend over time?
3. What are the projected sales for Q4 of 2016?
4. How well is each agent performing over time?
5. Are current social media efforts contributing to overall sales?

The first two questions pertain to seasonality and sales trend over time. As a newer company, we predicted that sales were increasing over time as the firm's agents gained experience and widened their consumer base. We also hypothesized that seasonality would reflect the school cycle, so we wanted to determine what specific months actually showed increases or decreases in sales. By quantitatively determining these spikes and dips, we hoped to provide suggestions as to how 24th Street Realty could allocate its marketing and labor resources more efficiently.

In addition, 24th Street Realty wanted to know what their sales would be for Q4 of 2016. By creating a forecasting model for future quarters, the firm can plan business logistics to ensure that they have enough leasing agents to respond to demand and continue providing top-quality service to their customers.

The last two questions relate to how individual leasing agents and current social media efforts contribute to overall sales. Close rates, or the rate at which agents convert appointments into a sale, are extremely important in real estate and management likes to see efficiencies. Because the skill and service level of an agent largely factors into closing a deal, answering this question can help 24th Street Realty determine if it needs to change its lead distribution system to account for the strengths/weaknesses of each agent.

For social media, we wanted to figure out if the company's Facebook and Twitter posts were actually helpful in leading customers to 24th Street Realty--whether that be generating leads or actual appointments. Because deals are the product of successful appointments, this metric directly affects overall sales. The results of this analysis will determine if 24th Street Realty needs to modify their social media strategy to drive more leads and ultimately sales.

MARKETING ANALYTICS TECHNIQUES AND RESULTS

We decided to use many different techniques that we had learned in class to answer the above marketing analytics questions. By using multiple techniques, we could diversify our analysis and create detailed visualizations for our client. Below, we have outlined the primary techniques we used: Multiplicative/Additive Models, Moving Averages, Ranked Averages with Sensitivity Analysis, and Multiple Linear Regression.

Multiplicative/Additive Models

As a neighborhood close to both campus and a major metropolitan area, there is a decent amount of seasonality in the Campus and Central Austin real estate business. Depending on the time in the year--or for many looking to lease, the semester--there are drops and spikes in the amount 24th Street Realty invoices each month. In order to gain a better understanding of these trends and their seasonality, we decided to look at the additive and multiplicative models for our data

set. After using Solver to forecast sales and compare them against the actual sales figures, we found the multiplicative model was the best fit because it had a lower standard deviation of residuals than the additive model (\$16,902.64 vs. \$17,211.52).

The results of the multiplicative model can be found in *Figure 1*, along with a graphical representation in *Figure 2*. The base of \$43,321.08 serves as the best estimate, without seasonality, invoiced at the beginning of the observed time period. The trend of 1.0111 in this model means that invoice amounts are increasing a rate of 1.11% per month. While we expected this percentage to be larger, it still confirms our prediction of overall growth and may be partially justified by the cyclical nature of student housing habits.

The seasonal indexes were more volatile, though. We found that the first four months of the year were by far the most successful, with April generating invoices 51% above an average month. This can be explained by the ending of the typical school year, and students' preparation for the following semester. Sales drop significantly below average during May (60% below) and June (20% below), presumably after most living arrangements for the next year have been made and students return home for the summer. We then see invoices rise 35% above average for July, possibly for transfer students and those who procrastinated making living arrangements during the spring. The following five months' percentages fluctuate below and above the average, reflecting the general volatility of the Campus and Central Austin housing market.

In addition to visualizing seasonality, we were able to use this analysis to create a predictive model for Q4 of this year. The forecasting equation is as follows:

$$\text{Forecasted Invoice} = (\$43,321.08) * (1.0111 ^{\text{month \#}}) * (\text{seasonal index})$$

While we already had sales figures for October 2016, our forecast predicted sales of \$74,738.65 and \$61,708.06 for November and December, respectively. These results can be seen in *Figure 1*.

Moving Averages

By using moving averages, we were able to smooth out the data and determine a trend. We wanted to know whether there was a trend in sales throughout the year and also over the previous three years. This filtered out the noise of seasonality to make insights clearer visually. Since we had 37 months of sales data, as seen in *Figure 3*, Excel calculated the moving averages trendline using twelve month periods.

As can be seen in *Figure 4*, 2014 experienced a steady upward trend in sales. The beginning of 2015 then saw a sharp decline in invoices, likely because students had either already leased an

apartment or were not interested in seeking 24th Street Realty's help. Later in 2015 there was a steady upward trend in the amount invoiced. However, in 2016 there has been another sharp drop in sales. Despite these fluctuations between years, overall sales have trended upward over time, increasing by an average of \$15,000 between 2014 and 2016.

Ranked Averages with Sensitivity Analysis

24th Street Realty has been collecting performance data on its 23 real estate agents since the beginning of 2014. Data on each agent was collected during the following stages of the purchase funnel: number of self generated leads, lead-to-appointment ratio, and close rate. However, not all of the agents worked consistently each month since the beginning of 2014; some agents were hired on later and some agents took some time off. In order to accurately compare the performance of the agents, we decided to calculate the average of each performance statistic for each agent and then rank them. Sensitivity Analysis was applied to eliminate any outliers.

Figures 5-7 show the ranked averages for each stage of the purchase funnel and *Figure 8* shows an overall ranking of each agent by combining their ranks from the three statistics. *Figures 5-7* are more useful to understand each agent's strengths, while *Figure 8* highlights overall performance.

One limitation of this method is the seasonality of sales. For example, if an agent takes off during a peak month for business, their average could suffer compared to another agent who worked during the peak month. The agent who worked during a busier month would then have an inflated average despite the possibility of better performance from another agent in slower months. We hope that by breaking down the average ranks at each level of the funnel, in addition to ranking each agent overall, the agents' performances will be more accurately reflected.

Multiple Linear Regression

Since 24th Street Realty had been collecting social media and sales data separately, we decided to combine all of the data into one spreadsheet to determine if we could find a relationship between the amount of office leads the company gets and the amount of engagement 24th Street Realty has with its followers on social media. This would help tell us if 24th Street Realty's marketing strategies were actually effective at bringing clients in. The best way we could think to analyze this data was to run a multiple linear regression. If the p-values for each variable were significant and the overall Significance F test was lower than 0.05, we could then use the coefficients of each variable to determine which form of social media engagement had the biggest impact on bringing leads to the firm.

The first time we ran the multiple linear regression we used the number of office leads as the dependent y-variable and the following eight characteristics as the independent x-variables: lead-to-appointment ratio, close rate, Twitter reach, Twitter engagement, number of tweets, FB

reach, FB engagement, and number of FB posts. The results of this initial regression can be seen in *Figure 9*. The only variables which we found to be significant, or close to being significant, were lead-to-appointment ratio, Twitter engagement, FB reach, and number of FB posts. The R-squared value was high at 0.99, but the overall Significance F test was not statistically significant so we decided to remove the insignificant variables and rerun the regression.

During the second regression we discovered that only Twitter engagements, number of FB posts, and FB reach were significant (*Figure 10*). We continued this process until the only variables left in the regression were significant, and the Significant F test was below 0.05. Our final model can be seen in *Figure 11*. With a relatively high R-squared value of 0.82 and a Significant F test of 0.002, we believe our model is a good fit. According to our model, the only significant variables in bringing in office leads are Twitter engagements and FB reach. The coefficients for each variable suggest that FB reach has the highest impact on gaining new office leads. Holding all other variables constant, for every additional 100 impressions of FB posts for the month, 24th Street Realty gains three new office leads.

RECOMMENDATIONS

Drawing from the results of our multiplicative model, we suggest that 24th Street Realty take seasonality into account in both their marketing efforts and resource allocation. January through April proved to generate invoices above average, indicating that agents are in high demand during this period. It would benefit 24th Street Realty to ensure it has enough agents hired during this time to continue providing the high-quality service it prides itself on. It is also important to note that these above-average sales are happening regardless of the firm's marketing efforts. This is reflected in the lower Facebook reach and Twitter engagement for these months seen in *Figure 12*. Therefore, we suggest that 24th Street Realty continue posting to its social accounts during the first four months of the year to keep themselves top-of-mind, but allocate their marketing push to months where sales have consistently been below average (i.e. May, June, August, October, and December).

To better track when appointments lead to deals, we suggest that 24th Street Realty survey their clients after they sign a deal to find which factors most influenced them to sign. One's purchase decision could be influenced by a variety of factors such as a referral from a friend, the level of service from the agent, or something else entirely. This allows the firm to see where opportunities exist to make improvements and ensure that they stay competitive in the future. They could even add these variables (i.e. count of referrals from friend, internet, etc.) to a multiple linear regression model to see if they have a significant impact on the amount invoiced per month.

We also suggest that 24th Street Realty attempt to utilize each agent's individual strengths. As shown in *Figure 5*, Agent Q has the most self-generated leads by far. However, *Figure 6* shows that he ranks 16th in the lead-to-appointment ratio. This could indicate that Agent Q has been unable to give an adequate amount of attention to the large number of leads that he has generated, thus hurting his ability to schedule appointments and ultimately close more deals. For this reason, 24th Street Realty should consider either changing the automated lead distribution system to take agents with too many leads out of the rotation, or incentivize agents to hand-off leads to agents with higher close rates (*Figure 7*). The firm could do this by setting a limit that once reached, allows agents to transfer their lead to a strong closer in exchange for a portion of the generated profit (given the agent is able to close the deal). This would encourage agents to work together rather than compete with each other. Further, in a service-based industry their success relies heavily on word of mouth. By investing their efforts in providing quality service from skilled professionals, both agents and clients benefit in the long run.

Lastly, data shows that 24th Street Realty's current social media strategy is in need of a revamp. Our analysis found that only Twitter engagements and FB reach were statistically significant in increasing the company's office leads. Rather than posting memes and movie quotes, 24th Street Realty should focus its content on information relevant to its services, such as customer testimonials or apartment listings around West Campus that new clients would find interesting. It could even incentivize people to follow its account or share its posts by hosting contests for 24th Street Realty swag. This would both increase engagement online and serve as free advertising around campus. Another simple way to increase the amount of impressions on a post is to "boost" its visibility (specifically to those who may not already follow you) by paying a small amount of money to Facebook. In combination, we feel these strategies could positively impact 24th Street Realty's social presence and generate more potential leads.

APPENDIX
